

Water Level & Flow Update for the Lower Nelson River

Weekly Update # 1 0 March 13 2020

Lower Nelson River (Split Lake to Hudson Bay)

Watering up activities started at Keeyask on February 26, 2020

Flows on the Nelson River are high as heavy Fall rainfall in the southern parts of the watershed flows north on its way to Hudson Bay - this will continue all winter. Hydro system flows to Split Lake and the Lower Nelson River come from 2 sources – Lake Winnipeg (LW) outflows through Kelsey generating station (at 3100 cms or 109,500 cfs) and Churchill River Diversion (CRD), through Notigi control structure (950 cms or 33,500 cfs). These combined flows (of 4,050 cms or 143,000 cfs) have been relatively constant since early December. The Nelson's flow downstream of Keeyask is 4340 cms (or 153,300 cfs) (measured at Limestone GS).*(See Map)*

Nelson River flow depends on Lake Winnipeg Water level:

Lake Winnipeg outflows are largely controlled by the Jenpeg Generating Station (upstream of Kelsey Generating Station). These flows are maximized every winter to allow as much water as possible to flow out of Lake Winnipeg to fuel generating stations on the Nelson River to meet heating demands by Manitobans. The maximum amount of water flow (termed *maximum discharge*) changes depending on the level of Lake Winnipeg – last year with Lake Winnipeg almost 2 feet lower, maximum discharge through Jenpeg was 66,000 cfs; while this year with the lake almost 2 feet higher, maximum discharge has been 92,000 cfs! Very similar conditions were experienced in Jan/Feb 2011 with Lake Winnipeg and Jenpeg outflows at similar high levels.

As of March 11, Lower Nelson River lake and forebay levels are:

- Split Lake 168.09 m (or 551.5 ft)
- Clark Lake 167.66 m (or 550.1 ft)
- Gull Lake 156.09 m (or 512.1 ft)
- Stephens Lake 140.41 m (or 460.7 ft)
- Long Spruce forebay 110.4 m (or 361.0 ft)
- Limestone forebay 84.98 m (or 278.8 ft)

Graphs of Split, Clark and Gull Lakes and Nelson River flow are available on the following pages.

Changing ice conditions at Split Lake's outflow through Clark Lake can cause water levels to fluctuate quickly on Split Lake as either ice forms and backs up water in the lake, or melts and releases more water downstream. Since early December water levels on these lakes have fluctuated due to ice conditions by almost 2.0 feet, while hydro system operations have remained relatively constant.

This update is based on a combination of current and forecasted weather data from Environment and Climate Change Canada; recent and historic stream flow conditions based on both federal and Manitoba Hydro data.
