## SUMMARY

## Background

The Keeyask Hydropower Limited Partnership (KHLP) was required to prepare a plan to monitor the effects of construction and operation of the Keeyask Generating Station (GS) on the environment. Besides measuring the accuracy of the predictions made and actual effects of the GS on the environment, monitoring results will provide information on how construction and operation of the GS will affect the environment and if more needs to be done to reduce harmful effects.

Construction of the Keeyask GS began in mid-July 2014 with the construction of cofferdams that blocked flow in the north and central channels of Gull Rapids (see instream structures map below). During the winter of 2015/2016, the Spillway Cofferdam, which partially blocks the south channel, was constructed. Beginning late in 2016 and continuing in 2017, the Tailrace Cofferdam was constructed. Work was completed in fall 2017 with the exception of an opening that was left to allow fish movement into and out of the cofferdam over the 2017/18 winter. This opening was closed in spring 2018, and the area was dewatered. The spillway was commissioned in August 2018. The South Dam Cofferdam was completed in fall 2018, blocking the channel and forcing the entire flow of the river through the spillway. In 2019, almost all work was done in the dry and included the excavation of the tailrace, construction of the tailrace spawning shoal, and completion of the dams and dykes.

Lake Sturgeon were identified as one of the key species for monitoring. They were chosen because they are culturally important to partner First Nations, local sturgeon populations have been previously impacted, and construction and operation of the GS will change or negatively impact important habitat. The plan to monitor the impacts of GS construction and operation on sturgeon includes several types of studies:

- Estimating the number of adults;
- Estimating the number and growth of juveniles (less than 800 millimetres [mm] in length);
- Identifying spawning locations and numbers of spawning fish; and
- Movement studies to record seasonal habitat use, long distance movements, and movements past barriers (i.e., over GSs or Gull Rapids).

The mitigation and offsetting plan for Lake Sturgeon included a commitment to a long-term stocking program. This plan addressed the loss of spawning habitat at Gull Rapids during the construction and initial years of operation (i.e., before the constructed spawning habitat is fully effective) by releasing young sturgeon into Stephens Lake. Stocking will also support the recovery of the sturgeon populations in Gull Lake, Stephens Lake, and the Upper Split Lake Area. Stocking began in 2014, with locations alternated between years (future Keeyask

Aquatic Effects Monitoring Plan
reservoir and Stephens Lake are stocked with fish born in even years, Burntwood River is stocked with fish born in odd years) and its effectiveness is assessed through juvenile population monitoring.

This report presents results of juvenile Lake Sturgeon population monitoring conducted during fall 2019. Data from juvenile populations in the study area have been collected intermittently since 2007 and the juvenile population monitoring study was conducted for the first time in 2014. The plan is to conduct juvenile population monitoring annually until 2044. Each year, sampling will be conducted using the same capture methods, so that results can be compared between different years and trends can be seen.

Aquatic Effects Monitoring Plan

Satellite Imagery - October, 2019

Map illustrating instream structures at the Keeyask Generating Station site, October 2019.

Map of the study area for the juvenile Lake Sturgeon population monitoring program. Sampling is done in the Upper Split Lake, the future Keeyask reservoir and the Stephens Lake areas every year.

Aquatic Effects Monitoring Plan

## Why is the study being done?

Juvenile Lake Sturgeon population monitoring is being done to answer several questions:
Does recruitment of wild sturgeon occur upstream and/or downstream of the GS during construction?

This question is important because if no young sturgeon are born during the seven year construction period, then in the future fewer adult sturgeon will be reproducing.

Is there a change in condition factor and growth of juvenile sturgeon during construction?
This question is important because if sturgeon become fatter or skinnier than they used to be, then something is changing in their environment. If the condition of juveniles decreases, it can also mean that stocking is adding too many fish to the environment and they cannot find enough food. In that case, the stocking plan will be adjusted.

What is the survival rate of stocked sturgeon?
This question is important because if the survival rate is high then the number of fish stocked may be reduced. If the survival rate is low, then the stocking plan would be adjusted (e.g., may change time or location of release).

What is the proportion of hatchery-reared to wild recruits within a birth year (i.e., how successful is the stocking program)?

The answer to this question will also tell us about the effectiveness of the stocking program.

Juvenile (left) and young-of-the-year (right) Lake Sturgeon.

## What was done?

Sampling was conducted in the Upper Split Lake Area (including the Burntwood River and Split Lake), the future Keeyask reservoir (the Nelson River between Clark Lake and Gull Rapids), and Stephens Lake in the fall of 2019. Gill nets were used to catch juvenile sturgeon, defined as those that are less than 800 mm in length. The gill nets were set in deep water habitats preferred by juveniles. When a fish was caught, it was measured and weighed. If the fish was
not already tagged, then two different tags were applied: an external (Floy ${ }^{\circledR}$ ) tag and a small PIT tag to make sure the fish is identifiable if one tag is lost. If the captured fish had already been tagged, then the tag numbers were recorded before the fish was released. Tagging and recapturing fish makes it possible to determine how much a fish grew or the distance they moved. It also makes it possible to estimate how many sturgeon are in a population. An ageing structure (a small piece of fin) was also collected to determine the year that the fish was born.

Captured juvenile Lake Sturgeon in a fish tub (left); measuring (middle); and weighing (right) a Lake Sturgeon after capture.

## What was found?

A total of 182 Lake Sturgeon were captured in the Upper Split Lake Area: 19 in the Burntwood River (all juveniles) and 163 in Split Lake proper ( 141 juveniles and 22 adults). Since sampling began in the Burntwood River, sturgeon born in every year from 2000 to 2018 have been caught. No Lake Sturgeon born in 2019 (called young-of-the-year [YOY]) were captured in the Upper Split Lake Area. Of the 182 sturgeon caught, eleven were wild fish tagged in a previous year and recaptured in 2019. Ten fish captured in Split Lake were raised at the Grand Rapids hatchery and released in the Burntwood River as one-year-olds: two in 2014 and eight in 2018. This is the largest number of hatchery fish released in the Burntwood River that have been caught in a single year.

A total of 244 Lake Sturgeon ( 234 juveniles and 10 adults) were captured in the future Keeyask reservoir. Four YOY sturgeon were captured, showing that sturgeon successfully reproduced in 2019 (no stocking of YOY took place in this area in 2019 prior to sampling). Of the 244 sturgeon, 21 had been tagged in a previous year (between 2008 and 2018), and an additional 57 were tagged hatchery-reared sturgeon released as one-year-olds in the Burntwood River (2014 and 2018) and the future Keeyask reservoir (2015, 2017 and 2019). Two of the recaptured hatchery fish were released 112 km and 129 km upstream in the Burntwood River in 2014 and 2018, respectively. Including the two fish caught in 2019, a total of six hatchery-reared fish released in the Burntwood River have been caught in the future Keeyask reservoir since stocking began in 2014. Analysis of growth between hatchery and wild caught fish showed that young hatchery fish are longer than wild fish of the same cohort. However, growth of hatchery fish appears to slow around age-5.

In Stephens Lake, 229 Lake Sturgeon (216 juvenile and 13 adult) were captured. No YOY (fish born in 2019) were captured in Stephens Lake. A total of 24 sturgeon tagged in a previous year
were recaptured, as well as 118 hatchery-reared sturgeon (released as one-year olds). Hatchery-reared sturgeon accounted for $52 \%$ of the total catch in Stephens Lake. Eleven of the hatchery-reared sturgeon were stocked in the future Keeyask reservoir, 105 were stocked in Stephens Lake, and one was stocked 138 km upstream in the Burntwood River. As in the future Keeyask reservoir, stocked hatchery fish were longer than wild fish of the same cohort, but showed slowed growth around age-5.

A computer model was used to generate estimates of population size and survival for wild juvenile Lake Sturgeon (i.e., those measuring less than 800 mm in length) in the Upper Split Lake Area, future Keeyask reservoir, and Stephens Lake. Previously, not enough fish had been recaptured in the Upper Split Lake Area for the model to work, so 2019 was the first year estimates were calculated. For the future Keeyask reservoir and Stephens Lake this is the second year where estimates were made for each population. In 2019, the Upper Split Lake Area (Burntwood River and Split Lake) juvenile population was estimated at 4,503 wild fish. Survival in this area was $82 \%$. The future Keeyask reservoir population in 2019 was estimated at 2,819 wild fish with a survival rate of $74 \%$. The Stephens Lake population in 2019 was estimated at 857 wild fish, and survival was estimated at $79 \%$.

A different model was also used to generate survival estimates for hatchery-reared fish stocked in the future Keeyask reservoir and Stephens Lake (not the Burntwood River because not enough hatchery-reared fish have been captured). Survival of fish stocked in the future Keeyask reservoir and Stephens Lake was estimated at $83 \%$ and $93 \%$, respectively. The population of hatchery fish in the future Keeyask reservoir was estimated to be 912, making up $24 \%$ of the total juvenile population. An estimated 1,318 hatchery fish were present in Stephens Lake, making up $61 \%$ of the total juvenile population.

As more data are collected and added to the models, the population and survival estimates are expected to become more precise and accurate. This is especially true for the Upper Split Lake Area as 2019 was the first time estimates could be calculated.

## What does it mean?

The capture of YOY sturgeon in 2019 shows that, like in 2015-2018, reproduction in the wild is occurring upstream of the Keeyask GS during construction. No YOY were captured in the Upper Split Lake Area or Stephens Lake but that does not mean reproduction was unsuccessful in 2019. Wild sturgeon have been born in each year since construction started (2015-2018) in the Upper Split Lake Area and the future Keeyask reservoir. In Stephens Lake, no wild fish from the 2018 cohort have been captured and no YOY fish were caught in 2019; however, the 20152017 cohorts are present in the catch.

The capture of many hatchery-reared sturgeon released as one-year-olds in the future Keeyask reservoir and Stephens Lake over the last three study years suggests the stocking program is having a positive effect on juvenile abundance in these areas. It demonstrates that stocked sturgeon are surviving in the wild and that they are growing after release. Few hatchery-raised fish released as one-year-olds in the Burntwood River have been recaptured; however,
recaptures have occurred as far downstream as the future Keeyask reservoir and Stephens Lake. The recapture of fish in Split Lake suggests that both stocked and wild fish are moving downstream out of the Burntwood River. Future sampling will likely focus more in Split Lake where fish have been recaptured.

What will be done next?
Monitoring will continue each fall until 2044. Further monitoring will show whether impoundment and subsequent operation of the Keeyask GS is affecting the growth of juveniles in the future Keeyask reservoir and Stephens Lake, and whether sturgeon continue to reproduce. Survival, growth, and population size of stocked and wild juveniles will continue to be assessed.

## ACKNOWLEDGEMENTS

We would like to thank Manitoba Hydro for the opportunity and resources to conduct this study.
Leslie Flett, Jason Beardy, Kelvin Kitchekeesik, and Tyler Kitchekeesik of Tataskweyak Cree Nation, and Graydon Brightnose of War Lake First Nation are thanked for their local expertise and assistance in conducting the field work.

The collection of biological samples described in this report was authorized by Manitoba Agriculture and Resource Development (previously Manitoba Sustainable Development), Fisheries Branch, under terms of the Scientific Collection Permit \#18-19.

### 1.0 INTRODUCTION

The Keeyask Generation Project (the Project) is a 695-megawatt (MW) hydroelectric generating station at Gull Rapids on the lower Nelson River in northern Manitoba. The Project is approximately 725 kilometres (km) northeast of Winnipeg, 35 km upstream of the existing Kettle Generating Station, where Gull Lake flows into Stephens Lake, 60 km east of the community of Split Lake, 180 km east-northeast of Thompson, and 30 km west of Gillam (Map 1). Construction of the Project began in July 2014.

The Keeyask Generation Project: Response to EIS Guidelines, completed in June 2012, provides a summary of predicted effects and planned mitigation for the Project. Technical supporting information for the aquatic environment, including a description of the environmental setting, effects and mitigation, and a summary of proposed monitoring and follow-up programs, is provided in the Keeyask Generation Project Environmental Impact Statement: Aquatic Environment Supporting Volume (AE SV). As part of the licensing process for the Project, an Aquatic Effects Monitoring Plan (AEMP) was developed detailing the monitoring activities of various components of the aquatic environment, including the focus of this report, juvenile Lake Sturgeon populations, for the construction and operation phases of the Project.

For the purposes of this monitoring program, Lake Sturgeon that are 800 mm in fork length or longer are classified as adults and smaller sturgeon are considered juveniles. Although fish greater than 800 mm length may not yet be sexually mature and may not reach sexual maturity for some years, this length was used as the threshold to distinguish between juveniles and adults because the smallest mature fish captured to date has been 809 mm (captured in 2016 in Stephens Lake; Legge et al. 2017).

Juvenile population monitoring is a key component of the overall Lake Sturgeon monitoring program. The Project is predicted to affect sturgeon recruitment by altering spawning habitat at Gull and Birthday rapids. Stocking aims to assist the recovery of sturgeon populations in the Upper Split Lake Area (i.e., the Burntwood River and the Nelson River between the Kelsey GS and Split Lake) and in the future Keeyask reservoir and Stephens Lake. Stocking is a key component of the offsetting plan, with stocking locations alternating between years (future Keeyask reservoir and Stephens Lake are stocked with even-cohort years, Burntwood River is stocked with odd-cohort years). Results of juvenile population monitoring will determine the impact of the loss of spawning habitat earlier than would be possible using adult population monitoring data, allowing timely adaptive management and mitigation, if required. Results of juvenile population monitoring will also assist in assessing the effectiveness of stocking and identify whether changes to the stocking plan are required. Data collected during juvenile population monitoring will be used to measure population size and cohort strength, identify changes in condition factor, determine whether natural reproduction is occurring, assess the need for young-of-the-year (YOY) habitat creation, and determine whether stocked fish are surviving and growing.

Juvenile Lake Sturgeon studies have been conducted in Gull Lake (the future Keeyask reservoir) and Stephens Lake since 2007. Surveys were initiated in the Burntwood River in 2012 and in both the Nelson River downstream of the Kelsey GS and Split Lake in 2015. These studies have increased the understanding of YOY and juvenile abundance, distribution, habitat use, condition, size, and year-class strength (MacDonald 2009; Michaluk and MacDonald 2010; Henderson and Pisiak 2012; Henderson et al. 2011, 2013, 2015; Burnett et al. 2016, 2017, 2018; Burnett and Hrenchuk 2019). Results from the Burntwood River and Upper Split Lake show that recruitment has occurred each year over the previous 10 years (Henderson and Pisiak 2012; Henderson et al. 2013, 2015; Burnett et al. 2017, 2018; Burnett and Hrenchuk 2019). In both Gull and Stephens lakes, recruitment has also occurred fairly consistently over the past ten years, but until recently the cohort-frequency distribution has been dominated by a single cohort produced in 2008 (Henderson et al. 2011, 2013, 2015; Henderson and Pisiak 2012; Burnett et al. 2017, 2018; Burnett and Hrenchuk 2019). Fish from the 2008 cohort are becoming too large for the sample gear and are therefore contributing a smaller proportion of the catch in each waterbody.

Lake Sturgeon stocking is being conducted using wild caught broodstock from the Burntwood River and the future Keeyask reservoir. To maintain the genetic structure of each population, progeny from each broodstock location are released back into their respective rivers (i.e., Burntwood River progeny released back into the Burntwood River and future Keeyask reservoir progeny released back to the Nelson River in Gull and Stephens lakes). Stocking occurred for the first time in 2014 and has occurred annually since, with a variety of life stages (larvae, fingerlings, yearlings) being released (Table 1; Klassen et al. 2017, 2018, 2019, in prep.). Since 2017, no larvae or fingerlings have been released.

This report presents results from juvenile population monitoring conducted in the Upper Split Lake Area, future Keeyask reservoir, and Stephens Lake in 2019. The area downstream of the Kelsey GS was not sampled as part of the Upper Split Lake Area in order to focus on areas where hatchery fish stocked into the Burntwood River may be captured (i.e., the Burntwood River and Split Lake).

Juvenile monitoring is being conducted to address the following key questions relevant during the construction period, as described in the AEMP:

- Does recruitment of wild sturgeon occur upstream and/or downstream of the GS during construction?
- Is there a biologically meaningful (and statistically significant) change in condition factor and growth of juvenile sturgeon during construction?
- What is the survival rate of stocked sturgeon?
- What is the proportion of hatchery-reared to wild recruits within a cohort (i.e., how successful is the stocking program)?

Juvenile population monitoring data will be collected annually until 2044.

Aquatic Effects Monitoring Plan

### 2.0 STUDY SETTING

Juvenile population monitoring in 2019 was conducted at three locations: 1) the Upper Split Lake Area (Burntwood River and Split Lake); 2) the future Keeyask reservoir (i.e., the reach of the Nelson River between the outlet of Clark Lake and Gull Rapids), and 3) Stephens Lake.

The Burntwood River flows in a north-easterly direction from First Rapids for approximately 35 km prior to emptying into the western arm of Split Lake (Maps 1 and 3). It is unknown if First Rapids represents a natural barrier to upstream fish passage; however, it is assumed to be under high flow conditions. Hard substrates predominate in the main channel, while loose, fine sediments and associated macrophyte growth occur in many off-current areas.

Split Lake is located at the confluence of the Burntwood and Nelson rivers (Map 1). Due to the large inflows from the Nelson and Burntwood rivers, the lake has detectable current in several locations. Split Lake has maximum and mean depths of 28.0 m and 3.9 m , respectively, at a water surface elevation of 167.0 m above sea level (ASL; Lawrence et al. 1999). The surface area of Split Lake was determined to be 26,100 ha (excluding islands), with a total shoreline length, including islands, of 940.0 km (Lawrence et al. 1999). The numerous islands in Split Lake represent 411.6 km of the total shoreline.

Birthday Rapids is located approximately 10 km downstream of Clark Lake and 30 km upstream of Gull Rapids (Map 1). The drop in elevation from the upstream to downstream side of Birthday Rapids is approximately 2 m . The 14 km reach of the Nelson River between Birthday Rapids and Gull Lake is characterized as a large, somewhat uniform channel with medium to high water velocities. There are a few large bays with reduced water velocity and a number of small tributaries that drain into the Nelson River.

Gull Lake is a section of the Nelson River where the river widens, with moderate to low water velocity. Gull Lake is herein defined as the reach of the Nelson River beginning approximately 17 km upstream of Gull Rapids and 14 km downstream of Birthday Rapids, where the river widens to the north into a bay around a large point of land (Maps 1 and 5), and extending to the downstream end of Caribou Island, approximately 3 km upstream of Gull Rapids. Gull Lake has three distinct basins, the first extending from the upstream end of the lake downstream approximately 6 km to a large island; the second extending from the large island to Morris Point (a constriction in the river immediately upstream of Caribou Island); and the third extending from Morris Point to the downstream end of Caribou Island.

Gull Rapids, now the site of the Keeyask GS, was located approximately 3 km downstream of Caribou Island on the Nelson River (Map 1). Prior to construction, the rapids were approximately 2 km in length, and the river elevation dropped approximately 11 m along the 2 km length. Two large islands and several small islands occurred within the rapids, prior to the river narrowing; these features are within the Project footprint and have now been either dewatered, incorporated into the GS or will be flooded after impoundment (Map 2). A summary of construction activities is provided in Section 2.1.

Just below the Keeyask GS, the Nelson River enters Stephens Lake (Maps 1 and 7). Stephens Lake was formed in 1971 by construction of the Kettle GS. Between Gull Rapids and Stephens Lake, there is an approximately 6 km long reach of the Nelson River that, although affected by water regulation at the Kettle GS, remains riverine habitat with moderate velocity. After August 2018, all flow has been passed through the Keeyask GS spillway (see Section 2.1).

Construction of the Kettle GS flooded Moose Nose Lake (north arm) and several other small lakes that previously drained into the Nelson River, as well as the old channels of the Nelson River that now lie within the southern portion of the lake. Major tributaries of Stephens Lake include the North and South Moswakot rivers that enter the north arm of the lake. Looking Back Creek is a second order stream that drains into the north arm of Stephens Lake (Map 1). Kettle GS is located approximately 40 km downstream of Gull Rapids.

### 2.1 CONSTRUCTION SUMMARY

Construction of the Keeyask GS began in mid-July 2014 with the construction of cofferdams in the north and central channels of Gull Rapids (Map 2). These cofferdams resulted in the dewatering of the north and central channels and the diversion of all flow to the south channel. Construction of the Spillway Cofferdam (SWCD), which extends into the south channel of Gull Rapids, was completed in 2015. The rock placement for the inner and outer groins of the Tailrace Cofferdam (TRCD) started in late 2016 and the impervious fill placement was completed in fall 2017. An opening was created to allow fish to move freely over the winter of 2017-2018. The opening was closed in spring 2018 and dewatering of the TRCD occurred in July, at which time a fish salvage was completed. In preparation for commissioning of the spillway, the SWCD was watered-up on both sides of the structure in June 2018. Removal of the SWCD started in early July and continued into August. The spillway was commissioned between August 3 and 7, 2018. Closing the south channel with the upstream South Dam Cofferdam (SDCD) commenced at the beginning of August and river closure was achieved on August 16. This closure and the work that continued to seal the cofferdam forced the entire river flow through the spillway. The downstream SDCD was completed in September and the area between the two cofferdams was dewatered, allowing for fish salvage to be completed by late September 2018. Work continued on the upstream SDCD until it was complete in late fall 2018. Almost all work in 2019 was in the dry. The construction activities included the excavation of the tailrace, construction of the tailrace spawning shoal, and completion of the dams and dykes.

### 2.2 Flows and Water Levels

From October 2018 to October 2019, calculated Split Lake outflows ranged from about 2,600 to $3,700 \mathrm{~m}^{3} / \mathrm{s}$. However, over most of the period, outflows ranged from approximately 3,000 to $3,500 \mathrm{~m}^{3} / \mathrm{s}$ and were near the historical annual median flow of approximately $3,300 \mathrm{~m}^{3} / \mathrm{s}$. Outflow increased from about 2,600 to $3,600 \mathrm{~m}^{3} / \mathrm{s}$ from October to December 2018, and then
was variable through the remainder of the winter period. Between June and September 2019, the flow generally ranged from 3,300 to $3,500 \mathrm{~m}^{3} / \mathrm{s}$. Flows dropped to about $2,900 \mathrm{~m}^{3} / \mathrm{s}$ in early October 2019 before rising again to almost $3,700 \mathrm{~m}^{3} / \mathrm{s}$ by the end of the month. Water levels varied in conjunction with flows, ranging from about 153.2-155.0 m ASL on Gull Lake.

### 3.0 METHODS

### 3.1 GilLNetting

A standardized sampling methodology has been developed for sampling juvenile sturgeon in Boreal Shield rivers using data sets collected from several populations in the Hudson Bay drainage basin (McDougall et al. 2014). This standardized methodology (described below) is being used to enable comparisons of cohort strength, abundance, growth, and condition among years. The gillnetting methods described below have been used to capture juvenile Lake Sturgeon during environmental studies related to the Keeyask Generation Project since 2008.

Gillnetting was conducted in the Upper Split Lake Area, the future Keeyask reservoir, and the upper 10 km of Stephens Lake. Two locations were sampled in the Upper Split Lake Area: the Burntwood River between First Rapids and Split Lake, and Split Lake proper. Prior to 2018, the Nelson River between the Kelsey GS and Split Lake was also sampled. This area was not sampled in 2019, and effort was focused on the Burntwood River and Split Lake as a means to locate stocked fish. Sites in Split Lake were chosen based on depth (greater than 5 m ) to try and target juvenile Lake Sturgeon. Gill nets were composed of five panels of 1, 2, 3, 5, and 6" twisted nylon stretched mesh ( $25,51,76,127$, and 152 mm ). Each panel was 25 yards (yd) $(22.9 \mathrm{~m})$ long and $2.7 \mathrm{yd}(2.5 \mathrm{~m})$ deep. Mesh sizes were staggered in the order of $1,5,2,6$, and 3 " to capture small and large juveniles across the length of each gang.

Gill nets were set in deep-water habitats (average depth $=11.6 \mathrm{~m}$ ) since YOY and juvenile Lake Sturgeon have been found to prefer these areas in the Winnipeg, Burntwood, and Nelson rivers (Barth et al. 2009; Michaluk and MacDonald 2010; McDougall et al. 2013; Henderson et al. 2014). Each gillnet set was given a unique identification number, and net locations were recorded using a Garmin Etrex GPS receiver (Garmin International Inc., Olathe, KS). Water depth at each end of the net was measured using a PiranhaMax Series 150 Portable Sonar (Humminbird, Eufaula, AL). Water temperature was measured daily in each area using a handheld thermometer $\left( \pm 0.5^{\circ} \mathrm{C}\right)$. HOBO Water Temperature Pro data loggers $\left( \pm 0.2^{\circ} \mathrm{C}\right)$, set approximately 1 m off the substrate, were also used to log water temperature at 6 -hour intervals in Gull and Stephens lakes. Gill nets were checked approximately every 24 hours, weather permitting. For comparability among years, similar gillnetting locations were used during juvenile monitoring programs conducted from 2014 to 2018. However, some sites have changed between years depending on water levels and flows. Locations and site-specific physical measurements collected at gillnetting sites in 2019 are found in Appendix 1.

### 3.2 BIOLOGICAL SAMPLING

All fish captured were counted by species and location. Lake Sturgeon were measured for fork length (FL; $\pm 1 \mathrm{~mm}$ ), total length ( $\pm 1 \mathrm{~mm}$ ), and weight ( $\pm 5 \mathrm{~g}$ using a digital scale, or nearest 25 g for fish greater than $4,000 \mathrm{~g}$ ).

For age analysis, the first fin ray of the left pectoral fin was removed immediately adjacent its articulation from each juvenile Lake Sturgeon captured for the first time. In cases where Lake Sturgeon had been previously aged, the first fin ray of the right pectoral fin was collected. If fish appeared to have been aged twice before or had deformed pectoral fins, ageing structures were not collected. All collected fin rays were placed in individually numbered envelopes, air dried, and brought back to the North/South Consultants Inc. laboratory for ageing (Section 3.4).

Small samples ( $1-2 \mathrm{~cm}^{2}$ ) were removed from the left pelvic fin of each Lake Sturgeon and preserved in 95\% Biological Grade Ethanol for potential future genetic analysis.

Ageing structures and genetics samples were not taken from YOY fish due to concerns of harming the small fish. Ages were inferred based on size (i.e., fish smaller than 150 mm FL ).

### 3.3 TAGGING

Lake Sturgeon greater than 250 mm FL were marked with individually numbered external Floy-GD-94 T-bar (FT) anchor tags (Floy-tag Inc., Seattle, WA). Floy-tags were inserted into the base of the dorsal fin using a Dennison Mark II tagging gun (Avery Dennison Corporation, Pasadena, CA).

Uniquely numbered Passive Integrated Transponder (PIT) tags from Oregon RFID (Oregon RFID Ltd., Portland, OR) were also used to mark Lake Sturgeon. Those measuring greater than 250 mm FL received 12 mm HDX tags ( $12.0 \mathrm{~mm} \times 2.12 \mathrm{~mm} ; 0.1 \mathrm{~g}$ ) and those measuring less than 250 mm FL (smallest fish tagged was 99 mm ) received 8 mm FDX-B tags ( 8.0 mm x $1.4 \mathrm{~mm} ; 0.027 \mathrm{~g}$ ). YOY Lake Sturgeon were not tagged (with either a Floy or PIT tag) due to concerns of harming the small fish. Each Lake Sturgeon was scanned for an existing PIT tag using an Agrident APR 350 Reader (Agrident Ltd. Steinkippenstrasse, Germany). For each untagged fish, a PIT tag was injected under the third dorsal scute using an Oregon RFID tag injector needle, dipped in Polysporin ${ }^{\circledR}$ to minimize the risk of infection. Tags were injected parallel to the horizontal axis of the fish, into muscle tissue (not the body cavity). Following implantation or upon recapture, the tags were logged, and the last six digits manually recorded. Injector needles were sterilized in boiling water prior to the start of sampling and again upon sampling completion.

### 3.4 Ageing Analysis

Lake Sturgeon fin rays were hardened in an epoxy resin (Cold Cure ${ }^{\text {TM }}$ ) and two 0.7 mm fin sections were cut distally within 5 mm of the articulation using a Struers Minitom (Struers Inc. Cleveland, OH ) low-speed sectioning saw. Fin sections were mounted on glass slides using Cytoseal-60 (Thermo Scientific, Waltham, MA) and viewed at five times magnification under a compound microscope. Annuli (growth rings) were counted by three experienced readers (independently), without prior knowledge of fish length or weight, or ages assigned by other readers. If readers assigned different ages to a fish, either the modal age or the median age was chosen. The rate of three-reader agreement was calculated in percent (percentage). Examples of Lake Sturgeon ageing structures are provided in Appendix 3.

Lake Sturgeon ageing structures exhibit well-defined banding patterns characteristic of repeated summer (fast-growth) and winter (slow/non-growth) periods (McDougall and Pisiak 2014; Appendix A3-1). Ageing structures from hatchery-reared Lake Sturgeon have different banding patterns that complicate the ageing process (described in Burnett and Hrenchuk 2019).

In fish stocked at age-1, the weak annulus is often followed by the presence of a false annulus, not corresponding to slowed winter growth, but instead to stocking and the subsequent establishment period. The false annuli decrease ageing accuracy because they are difficult to distinguish from true annuli. Ageing structures were not collected from known hatchery fish in 2019, instead known ages were used.

Based on the ageing structures analyzed it appears PIT tag loss in hatchery released Lake Sturgeon is occurring, as several ageing structures from the Upper Split Lake Area, the future Keeyask reservoir and Stephens Lake exhibited annuli characteristic of hatchery fish (i.e., weak or missing first annuli). However, it could not be determined whether these fish are hatcheryreared or wild fish as weak/missing first annuli have been observed in the ageing structures of known wild fish. As such, these fish were included with wild fish for analyses.

### 3.5 Data Analysis

As was done in previous years, data were analysed for all sizes of Lake Sturgeon captured (as opposed to only those measuring less than 800 mm FL). Mesh sizes used select for small Lake Sturgeon but larger fish are also captured; therefore, including all fish in the summary statistics ensures comparability among years.

To better describe sampling locations, relative abundance (CPUE) and fish movements, each sampling area was divided into distinct geographical zones (Maps 3, 5, and 7).

Mean FL (mm), weight (g), and condition factor (K) were calculated for all Lake Sturgeon by location. In Stephens Lake and the future Keeyask reservoir, known hatchery and wild fish were
presented separately. Condition factor was calculated based on the following equation (after Fulton 1911, in Ricker 1975):

$$
K=W /\left(L^{3} / 10^{5}\right)
$$

Where:

$$
\begin{aligned}
& \mathrm{W}=\text { round weight }(\mathrm{g}) \text {; and } \\
& \mathrm{L}=\text { fork length }(\mathrm{mm}) .
\end{aligned}
$$

Ageing structures were only collected for fish measuring < 800 mm FL. Because fish approach this length by age nine, all age analyses were restricted to fish aged 0-9 years as the full range of sizes for older fish would not be included in the sample.

Mann-Whitney U-Tests and t-tests were used to compare mean fork length-at age, mean weight-at-age, and mean condition factor-at-age for known hatchery-reared and wild Lake Sturgeon. Statistical comparisons were only conducted where sample sizes were greater than eight individuals. Significance level was set at 0.05 (5\%).

A von Bertalanffy growth curve was generated from all age and length data collected during the study to compare the growth of wild vs. hatchery-reared fish, as well as wild fish captured during baseline vs. construction for fish aged as nine years or less. Fish older than age-9 were not included in the analysis as they are not fully represented in the catch (ageing structures are not collected from fish >800 mm fork length, which corresponds to fish older than age-9). Growth comparisons between hatchery and wild fish were truncated at age-5 (the age of the oldest hatchery fish captured) to make the curves comparable. Hatchery fish stocked in the Burntwood River but captured in the future Keeyask reservoir and Stephens Lake were excluded from the analyses in order to keep the data comparable. These fish are genetically distinct, which may impact their size. Further, these fish travelled a long distance downstream prior to capture which might impact their normal growth. The curve was calculated using the following equation:

$$
L=L_{\infty}\left(1-\mathrm{e}^{-k(t-t} 0\right)
$$

Where:
$t=$ age (years)
$\mathrm{t}_{0}=$ is the theoretical age at which FL is 0 ;
$L=$ is the fork length (mm) of the fish at age $t$;
$L_{\infty}=$ is the theoretical maximum TL that an individual in the population can attain; and
$\mathrm{k}=$ growth rate .
Length-frequency distributions were plotted in 50 mm length class intervals (e.g., 300-349 mm) and length-weight regression equations were derived using least squares analysis on logarithmic transformations of fork lengths and weights according to the following relationship:

$$
\ln (W)=\ln (a)+\ln (L)^{*} b
$$

Where:

$$
\begin{aligned}
& \mathrm{W}=\text { weight }(\mathrm{g}) ; \\
& \mathrm{L}=\text { fork length }(\mathrm{mm}) ; \\
& \mathrm{a}=\mathrm{Y} \text {-intercept; and } \\
& \mathrm{b}=\text { slope of the regression line. }
\end{aligned}
$$

Cohort frequency distributions were plotted for each location.
Gillnetting hours (i.e., effort) was calculated as the number of sampling hours per 100 m of net set using the following equation:

$$
\text { Effort (hours) }=\text { set duration } \times(\text { net length } / 100 \mathrm{~m})
$$

Catch-per-unit-effort (CPUE) was calculated and expressed as the number of fish captured in 100 m of net per 24-h period using the following formula:

$$
\text { CPUE }=\sum \text { \# Lake Sturgeon } / \sum \text { Effort } \times 24 \text { h }
$$

Where: $\Sigma=$ sum of the number of fish or gillnetting hours at all sites.
CPUE was calculated by geographical zone for each study location and study year.
Prior to 2018, hatchery-reared Lake Sturgeon were released as larvae, fingerlings, and yearlings. However, without additional analysis (genetics or isotopic signature in fin rays) fish can only be conclusively identified as hatchery-reared based on the presence of a PIT tag, which are exclusive to fish stocked at age-one. All fish not definitively identified as hatcheryreared (based on the presence of a PIT tag) were classified as "wild" in order to facilitate data analysis. As the additional analysis (genetics or isotopic signature in fin rays) has not been undertaken, it cannot be determined if fish belonging to cohorts corresponding to stocking events of larvae or fingerlings (e.g., a YOY captured in the Burntwood River in 2017) originated from the hatchery or a natural spawning event. Since 2018, only age-1 PIT tagged fish have been released.

### 3.6 Population Estimate

Mark-recapture population estimates have been calculated for the Upper Split Lake Area (years: 2012-2019), future Keeyask reservoir (years: 2010 and 2012-2019) and Stephens Lake (years: 2010 and 2012-2019). Only wild Lake Sturgeon classified as juveniles (i.e., FL < 800 mm ) were included in the population estimate.

The Jolly-Seber model (POPAN formulation; Arnason and Schwarz 2002), as implemented within MARK, was used to estimate the annual abundance of wild juvenile Lake Sturgeon in the upper Split Lake Area, future Keeyask reservoir, and in Stephens Lake. Detailed methods can be found in Appendix 5. Estimates are reported as a mean with 95\% confidence intervals (CI).

A Cormack-Jolly-Seber model was used to calculate a survival estimate for hatchery-reared juvenile Lake Sturgeon cohorts with a minimum number of recaptures $(\mathrm{n}=25)$ stocked in both

Aquatic Effects Monitoring Plan
the future Keeyask reservoir and Stephens Lake, using the probability of recapture in each year. The population of hatchery-reared Lake Sturgeon was estimated based on the total number of fish released multiplied by the survival estimate (e.g., 1,000 fish released and an $80 \%$ survival estimate would generate a population estimate of 800 individuals). The estimate is recalculated every year between stocking and the study year, to get the final estimate (e.g., 1,000 fish released in 2017 would generate a population estimate of 800 individuals in 2018, and 640 in 2019). The survival rate remains constant between years. A survival estimate for hatcheryreared juvenile Lake Sturgeon stocked in the Burntwood River as too few of these fish have been captured.

### 4.0 RESULTS

Gill net site data is presented in Appendix 1 and biological and tagging information for Lake Sturgeon captured in 2019 are provided in Appendix 2.

### 4.1 Upper Split Lake Area

Water temperature in the Upper Split Lake Area ranged from $14.0^{\circ} \mathrm{C}$ to $12.0^{\circ} \mathrm{C}$ over the course of the study (September 6 to 16, 2019; Appendix A1-1).

### 4.1.1 BURNTWOOD RIVER

In total, 96 fish, comprised of five species, were captured at 22 sites in the Burntwood River between September 6 and 11, 2019 (Tables 2 and 3; Map 3). Lake Sturgeon ( $n=19 ; 19.8 \%$ ) were the second most abundant species captured after Longnose Sucker ( $n=66 ; 68.8 \%$ ) (Table 3). Gillnet site data as well as biological and tagging information for all Lake Sturgeon captured in the Burntwood River are provided in Appendices A1-1 and A2-1. Nineteen juvenile Lake Sturgeon were captured in 641.4 gillnet hours, producing an overall CPUE of 0.71 LKST/100 m net/24 h (Table 4). One Lake Sturgeon mortality occurred during sampling on 11 September (FL = $415 \mathrm{~mm} ; \mathrm{Wt}=460 \mathrm{~g}$; Appendix A2-1). Gill nets were set in all three zones of the Burntwood River below First Rapids (Map 3). Total CPUE by zone was as follows:

- 0.31 LKST/100 m net/24 h in Zone BWR-A ( $\mathrm{n}=5$ sites);
- 0.00 LKST/100 m net/24 h in Zone BWR-B ( $\mathrm{n}=2$ sites); and
- $0.93 \mathrm{LKST} / 100 \mathrm{~m}$ net/24 h in Zone BWR-C ( $\mathrm{n}=15$ sites; Table 4).

Total CPUE values for the Burntwood River catch since 2012 are presented in Table 5. Total CPUE in 2019 was comparable to 2018, but lower than sampling conducted between 2012 and 2017 (range: 0.78-1.37 LKST).

### 4.1.1.1 Year-Class Strength

Ageing structures were collected from all 19 Lake Sturgeon. Aged Lake Sturgeon ranged from 1 to 19 years old, with the 2013 ( $\mathrm{n}=5$; age-6) and 2016 ( $\mathrm{n}=3$; age-3) cohorts accounting for $26.3 \%$ and $15.8 \%$ of the catch, respectively (Figure 1). No YOY (2019 cohort) Lake Sturgeon were captured. Three Lake Sturgeon with a FL of $<800 \mathrm{~mm}$ where aged considerably older than the 9-year mark typically assigned to this size, measuring $518 \mathrm{~mm}, 649 \mathrm{~mm}$, and 694 mm , ages 12, 19, and 19, respectively). All cohorts fully recruited to the sampling gear (i.e., 2010-2018) were captured other than the 2015 cohort. A cohort frequency histogram that includes all wild juvenile Lake Sturgeon captured during juvenile monitoring in the Burntwood River between

Aquatic Effects Monitoring Plan

2011 and 2019 are presented in Table 6. Every cohort between 2000 and 2018 has been represented in the catch since studies began.

### 4.1.1.2 Growth and Condition

All Lake Sturgeon were classified as juveniles based on their length (<800 mm FL). Captured juvenile Lake Sturgeon had a:

- Mean FL of $430 \mathrm{~mm}(\mathrm{n}=19$; standard deviation [StDev] = 114 mm ; range 275-694 mm);
- Mean weight of $609 \mathrm{~g} \mathrm{( } \mathrm{n}=19$; StDev = 531 g ; range $100-2,120 \mathrm{~g}$ ); and
- Mean condition factor of $0.62(\mathrm{n}=19 ; \mathrm{StDev}=0.06$; range $0.48-0.71)$ (Table 7).

Lake Sturgeon in the 400-449 FL interval were captured most frequently, representing 31.6\% of the total catch (Figure 2). The length-weight relationship derived for Lake Sturgeon captured in the Burntwood River is presented in Figure 3.

### 4.1.1.3 RECAPTURES

No previously tagged or hatchery-reared juvenile Lake Sturgeon were captured in the Burntwood River in 2019.

### 4.1.2 Split Lake

In total, 323 fish, comprised of 12 species, were captured at 18 sites in Split Lake between September 11 and 16, 2019 (Table 2; Map 3). Lake Sturgeon (141 juveniles and 22 adults) were the most abundant, accounting for $50.5 \%$ of the total catch (Table 3). A total of 722.7 gillnet hours were fished producing an overall Lake Sturgeon CPUE of 5.41 LKST/100 m net/24 h (Table 4). Three juvenile mortalities (1.8\%) occurred during sampling (see Appendix A2-1 for biological information). Gillnet site data as well as biological and tagging information are provided in Appendices A1-1 and A2-1. Annual CPUE values for the Split Lake catch since 2015 are presented in Table 5. Total CPUE in 2019 was more than double the value recorded in any previous sampling year (range: 0.75-2.60 LKST), however, sampling locations differed from previous years so the increase in CPUE cannot be interpreted as an increase in the Lake Sturgeon population.

Of the 163 Lake Sturgeon captured, 10 were known hatchery-reared fish (i.e., stocked as age-1 and marked with PIT tags; discussed further in Section 4.1.2.4). Total CPUE for wild and hatchery-reared Lake Sturgeon was as follows:

- 5.08 LKST/100 m/24 h ( $\mathrm{n}=153$ ) for wild Lake Sturgeon; and
- $0.33 \mathrm{LKST} / 100 \mathrm{~m} / 24 \mathrm{~h}(\mathrm{n}=10)$ for hatchery-reared Lake Sturgeon (Table 8).

### 4.1.2.1 Year-Class Strength

Ageing structures were collected from 124 of the 141 juvenile fish captured. Ageing structures were not collected from two fish that were released quickly after being wrapped badly in the net to prevent mortality. Structures were not collected from an additional ten fish that were knownage hatchery fish and five that had been aged in a previous year. One ageing structure had a crystalline center and could not be accurately aged. Thus, ages were assigned to 138 of 141 juvenile Lake Sturgeon captured in Split Lake.

Lake Sturgeon ranged from 1 to 15 years old and represented the 2004 and 2007-2018 cohorts (Table 6; Figure 4). No YOY (i.e., 2019 cohort) fish were captured. The 2013 cohort (age-6) was the most abundant, accounting for $34.1(n=47)$ of the catch. Lake Sturgeon from the 2011 ( $n=14 ; 10.1 \%$ ), 2014 ( $n=14 ; 10.1 \%$ ), and $2017(n=13 ; 9.4 \%)$ cohorts were also caught relatively frequently (Figure 4). Cohort frequencies for all wild juvenile Lake Sturgeon captured in Split Lake from 2015 to 2019 are presented in Table 6. Every cohort between 2003 and 2018 has been represented in the catch.

### 4.1.2.2 Growth and Condition

In 2019, 153 wild (including adult size fish) and 10 known hatchery-reared Lake Sturgeon were captured. Length-weight relationships for hatchery-reared and wild Lake Sturgeon are presented in Figure 3.

Wild Lake Sturgeon had a:

- Mean FL of $606 \mathrm{~mm}(\mathrm{n}=153$; StDev = 168 mm ; range 161-1,000 mm);
- Mean weight of $1,553 \mathrm{~g}(\mathrm{n}=130$; StDev $=994 \mathrm{~g}$; range $40-3,860 \mathrm{~g})$; and
- Mean condition factor of $0.72(\mathrm{n}=130 ;$ StDev $=0.08$; range $0.35-0.91$ ) (Table 9).

Wild Lake Sturgeon from the $500-549 \mathrm{~mm}, 550-599 \mathrm{~mm}$ and $700-749 \mathrm{~mm}$ FL intervals were captured most frequently, each accounting for $13.7 \%(n=21)$ of the catch (Figure 2).

Hatchery Lake Sturgeon had a:

- Mean FL of $364 \mathrm{~mm}(\mathrm{n}=10$; StDev $=66 \mathrm{~mm}$; range 304-481 mm);
- Mean weight of $335 \mathrm{~g}(\mathrm{n}=10$; StDev = 212 g ; range 160-740 g); and
- Mean condition factor of $0.63(\mathrm{n}=10$; StDev $=0.06$; range $0.54-0.74)$ (Table 10).

Hatchery reared Lake Sturgeon from the 300-349 mm FL interval were the most frequently captured size-class accounting for $60.0 \%(\mathrm{n}=6)$ of the catch (Figure 2). The $350-399 \mathrm{~mm}$ $(n=2)$ and $450-499 \mathrm{~mm}(\mathrm{n}=2)$ FL intervals were also present, each accounting for $20.0 \%$ of the catch.

### 4.1.2.3 Recaptures

Eleven wild Lake Sturgeon (three adults and eight juveniles) tagged in previous years were captured (Table 11; Appendix A4-1). Two juvenile fish were originally tagged in the future Keeyask reservoir and were recaptured 74.7 km and 80.1 km upstream of their original capture locations. These two fish measured 655 and 631 mm when originally captured in 2014 and 2016, and measured 796 mm and 718 mm , respectively, when recaptured in 2019. Three (two adults and one juvenile) were originally tagged in the Burntwood River and were recaptured between 22.7 and 48.3 km downstream of their original capture location. The remaining six fish (one adult and five juveniles) were originally tagged in Split Lake and were recaptured between $<0.1 \mathrm{~km}$ and 4.5 km of their original capture location.

### 4.1.2.4 Hatchery Captures

Ten hatchery fish (i.e., those PIT tagged and stocked as age-1) were caught in 2019, accounting for $6.1 \%$ of the total catch (Table 12; Appendix A4-2). This represents the largest capture of Lake Sturgeon stocked in the Burntwood River since stocking began in 2014. None of the hatchery-reared fish had been captured during previous sampling. An age breakdown of all the hatchery-reared fish captured between 2014 and 2018 is presented in Table 12.

Of the ten hatchery fish:

- Two were stocked on October 2, 2014.
- One was stocked at Site 2 (Zone BWR-B) and was caught 33.1 km downstream.
- One was stocked on the same day but its stocking site was not recorded. Considering all fish were stocked in the Burntwood River, this fish was captured at least 20 km downstream of its original stocking site.
- Five were stocked on May 31, 2018, at the Odei River boat launch (Site 1; Zone BWR-B; Map 4) and were captured between 27.0 and 30.6 km downstream of their stocking location.
- Three were stocked on June 7, 2018, just below First Rapids (Site 2; Zone BWR-A; Map 4) and were captured between 40.0 and 44.8 km downstream of their stocking location.

### 4.1.3 Upper Split Lake Area Population Estimate

The 2019 estimate for the juvenile segment of the population in the Upper Split Lake Area (including the Kelsey GS Area, the Burntwood River, and Split Lake) was 4,503 wild juvenile Lake Sturgeon ( $95 \% \mathrm{Cl}$ : $1,348-15,044$ ) (Figure 5; Appendix A5-1). This was above the $95 \% \mathrm{Cl}$ of the 2014 estimate, but within the $95 \%$ Cl's for 2012, 2013, and 2015-2018. The estimated annual survival rate was $82 \%$. Too few stocked fish were captured to create an estimate of the hatchery-reared Lake Sturgeon population.

Aquatic Effects Monitoring Plan

### 4.2 Future Keeyask reservoir

Ten species $(\mathrm{n}=545)$ were captured at 39 sites between September 10 and 20, 2019 (Tables 2 and 3; Map 5). Water temperature during sampling ranged from $12.9^{\circ} \mathrm{C}$ to $14.5^{\circ} \mathrm{C}$ (Appendix A12). Lake Sturgeon ( $n=244 ; 44.8 \%$ ) were the most abundant species (Table 3). Gillnet site data as well as biological and tagging information for all Lake Sturgeon captured are provided in Appendices A1-2 and A2-2.

In total, 234 juvenile and ten adult Lake Sturgeon were captured in 1,560.6 gillnet hours, producing an overall CPUE of 3.75 LKST/100 m net/24 h (Table 4). One juvenile mortality (0.4\%) occurred during sampling on September 18 (see Appendix A2-2 for biological information). Gill nets were set throughout Gull Lake (i.e., in zones GL-A, GL-B, and GL-C), as well as the first zone upstream of Gull Lake (i.e., BR-D) (Map 5). Total CPUE by zone, from upstream to downstream, was as follows:

- 2.92 LKST/100 m/24 h in Zone BR-D ( $\mathrm{n}=6$ sites);
- 1.53 LKST/100 m/24 h in Zone GL-A ( $\mathrm{n}=8$ sites);
- $5.22 \mathrm{LKST} / 100 \mathrm{~m} / 24 \mathrm{~h}$ in Zone GL-B ( $\mathrm{n}=13$ sites); and
- 3.72 LKST/100 m/24 h in Zone GL-C ( $\mathrm{n}=12$ sites; Table 4).

Total annual CPUE recorded in the future Keeyask reservoir since 2007 are presented in Table 5. Total CPUE in 2019 was the highest recorded since 2011.

Of the 244 Lake Sturgeon captured, 57 were known hatchery-reared fish (i.e., stocked as age-1 and marked with PIT tags; discussed in further detail in Section 4.2.5). Total CPUE for wild and hatchery-reared Lake Sturgeon was as follows:

- 2.88 LKST/100 m/24 h ( $\mathrm{n}=187$ ) for wild Lake Sturgeon; and
- $0.88 \mathrm{LKST} / 100 \mathrm{~m} / 24 \mathrm{~h}(\mathrm{n}=57)$ for hatchery-reared Lake Sturgeon (Table 8).

### 4.2.1 Year-Class Strength

Ageing structures were collected from 163 of the 234 juvenile fish captured. Of the fish not aged, 57 were known-age hatchery fish, four were not aged in 2019 but had been aged in a previous year, and four were considered YOY (age-0) based on size. Thus, ages were assigned to 228 juvenile Lake Sturgeon, including 171 wild and 57 hatchery fish. Ageing structures were not collected from six fish that had deformed fins that would prevent accurate ageing.

Lake Sturgeon (both wild and hatchery) ranged in age from 0 to 13 years (2006-2019 cohorts; Figure 6), with the 2016 cohort captured most frequently ( $\mathrm{n}=60 ; 26.3 \%$ ). The 2008, 2014, and 2018 cohorts were also relatively abundant in the catch, accounting for $13.2 \%(n=30), 14.0 \%$ ( $\mathrm{n}=32$ ), and $12.3 \%(\mathrm{n}=28)$, respectively. The 2008 cohort is likely underestimated as individuals from the cohort are now 11 years old, and some are likely > 800 mm FL. Four YOY

Aquatic Effects Monitoring Plan
fish (i.e., 2019 cohort) were captured in Zone GL-C. Known hatchery-reared fish accounted for $37.5 \%, 26.7 \%$, and $96.4 \%$ of the 2014, 2016, and 2018 cohorts, respectively (Figure 6).

Wild fish from all cohorts since 2000, with the exception of 2002, have been represented in the catch since studies began (Table 6).

### 4.2.2 POPULATION Estimate

The 2019 estimate for the future Keeyask reservoir population was 2,819 wild juvenile Lake Sturgeon (95\% CI: 1,529-5,199) (Figure 7; Appendix A5-2). This was within the $95 \% \mathrm{Cl}$ of the 2010-2018 estimates. The estimated annual survival rate was $74 \%$.

Survival of hatchery-reared Lake Sturgeon stocked into the future Keeyask reservoir was estimated at $83 \%$ (Appendix A5-3). Based on this survival estimate, 198, 316, and 398 hatchery-reared individuals from the 2014, 2016, and 2018 cohorts are predicted to still be present in the future Keeyask reservoir, contributing to a population estimate of 912 hatchery fish. Based on these numbers, it is estimated that hatchery fish currently make up $24 \%$ of the total juvenile Lake Sturgeon population in the future Keeyask reservoir.

### 4.2.3 GROWTH AND CONDITION

Length-weight relationships for hatchery-reared and wild Lake Sturgeon captured in the future Keeyask reservoir are presented in Figure 3.

Wild Lake Sturgeon had a:

- Mean FL of $502 \mathrm{~mm}(\mathrm{n}=187$; StDev = 178 mm ; range 95-1,060 mm);
- Mean weight of $1,294 \mathrm{~g} \mathrm{( } \mathrm{n}=183$; StDev = 1,430 g; range 100-8,550 g); and
- Mean condition factor of $0.68(\mathrm{n}=183$; $\mathrm{StDev}=0.11$; range $0.25-1.24)$ (Table 9).

Wild Lake Sturgeon in the 350-399 mm FL interval were captured most frequently, representing $19.8 \%(\mathrm{n}=37)$ of the wild catch (Figure 8). Fish measuring $450-499 \mathrm{~mm}$ and $300-349 \mathrm{~mm}$ were also frequently captured representing $12.3 \%(n=23)$ and $10.7 \%(n=20)$ of the wild catch, respectively (Figure 8).

Hatchery-reared Lake Sturgeon had a:

- Mean FL of $364 \mathrm{~mm}(\mathrm{n}=57$; StDev $=72 \mathrm{~mm}$; range 265-530 mm);
- Mean weight of $307 \mathrm{~g}(\mathrm{n}=56$; StDev $=214 \mathrm{~g}$; range 75-950 g); and
- Mean condition factor of $0.54(\mathrm{n}=56$; StDev $=0.12$; range $0.28-0.95$ ) (Table 10).

Hatchery-reared Lake Sturgeon in the 300-349 mm FL interval were captured most frequently, representing $29.8 \%$ of the hatchery catch $(\mathrm{n}=17)$ (Figure 8). Fish measuring $350-399 \mathrm{~mm}$ and

Aquatic Effects Monitoring Plan

250-299 mm were also frequently captured representing $24.6 \%(n=14)$ and $19.3 \%(n=11)$ of the hatchery catch, respectively (Figure 8).

A comparison of von Bertalanffy growth curves between baseline (2008-2012) and construction (2014-2019) monitoring years showed no difference between the two groups (Figure 9). Growth curve analysis of hatchery and wild fish showed that young hatchery fish ( $0-4$ years-old) are longer than wild fish of the same cohort. However, the lengths of wild and hatchery fish appear similar around age-5 (Figure 10).

### 4.2.4 ReCAPTURES

A total of 21 wild Lake Sturgeon tagged in a previous year were recaptured in 2019 (Table 11; Appendix A4-1). All fish were originally tagged in the future Keeyask reservoir: one in each of 2008, 2012, 2014, 2015, and 2016, seven in 2017, and nine in 2018.

Recaptured fish moved varying distances from their original capture locations:

- Ten moved less than 1.0 km .
- Seven were recaptured within $1.0-5.6 \mathrm{~km}$.
- Four were recaptured within 6.3-10.8 km.

### 4.2.5 Hatchery Captures

Fifty-seven known hatchery-reared Lake Sturgeon (i.e., those PIT tagged and stocked as age-1) were caught in 2019, representing $23.4 \%$ of the total catch (Table 12). An age breakdown of all hatchery-reared fish captured between 2014 and 2018 is presented in Table 13.

Of the 57 hatchery fish caught in the future Keeyask reservoir (Appendix A4-3):

- Twelve were stocked in Gull Lake in 2015 (Map 6):
- Five were stocked at Site 1 on June 22 (Zone GL-C). Four were caught between 0.3 and 2.7 km downstream of their release location and one was caught 3.0 km upstream.
- Three were stocked at Site 2 on June 22 (Zone GLC) and were caught between 0.3 and 0.8 km of their release location.
- Two were stocked at Site 6 on September 16 (Zone GL-B). One was caught 4.5 km downstream and the other 0.1 downstream of their release location; and
- Two were stocked at Site 7 on September 16 (Zone GL-C) and were caught 0.8 and 5.8 km upstream of their release location, respectively.
- Sixteen were stocked on June 8, 2017 in Zone GL-A (Site 1; Map 6):
- One was caught in Zone GL-A, 2.2 km downstream of its release location.
- Twelve were caught in Zone GL-B between 6.7 and 11.6 km downstream of their release location; and
- Three were caught in Zone GL-C, between 11.8 and 13.6 km downstream of their original release location.
- Twenty-seven were stocked in Gull Lake on June 6, 2019 (Map 6):
- Fifteen were stocked in Zone GL-C and were caught between 0.2 and 1.5 km from their release location; and
- Twelve were stocked in Zone GL-B and were caught between 0.1 and 4.4 km from their release location.
- Two were stocked in the Burntwood River:
- One was stocked on May 30, 2014 in Zone BWR-B (Site 2; Map 4) and was captured on September 13, 2019, in Zone GL-B, 111.9 km downstream of its release location. In the five years since release, the fish grew 267 mm in length and increased 568 g in weight; and
- One was stocked on June 7, 2018 in Zone BWR-A (Site 2; Map 4) and was captured on September 13, 2019, in Zone GL-B, 128.9 km downstream of its release location. Since release, the fish grew 97 mm in length and increased 140 g in weight.

### 4.3 Stephens LaKe

Forty gillnet sites were fished in upper Stephens Lake between September 11 and 21, 2019 (Table 2; Map 7). A total of ten fish species $(n=513)$ were captured, of which Lake Sturgeon were the most abundant ( $\mathrm{n}=229$; 44.6\%) (Table 3). Gillnet site data is presented in Appendix A1-3 and biological and tagging information are presented in Appendix A2-3.

In total, 216 juvenile and 13 adult Lake Sturgeon were captured in 1,560.9 gillnet hours for a total CPUE of 3.52 LKST/100 m net/24 h (Table 4). Total CPUE was the highest since monitoring began in 2007 (Table 5). Four juvenile (1.7\%) and one adult ( $0.4 \%$ ) mortality occurred during sampling (see Appendix A2-3 for biological information). Gill nets were set in both zones located within the upper 10 km of Stephens Lake (Map 7). Total CPUE by zone was as follows:

- 2.02 LKST/100 m/24 h in Zone STL-A ( $\mathrm{n}=8$ sites); and
- 3.91 LKST/100 m/24 h in Zone STL-B ( $\mathrm{n}=32$ sites; Table 4).

Of the 229 Lake Sturgeon, 118 ( $51.5 \%$ ) were known hatchery-reared fish (i.e., stocked at age-1 and marked with PIT tags; discussed in further detail in Section 4.3.5). Total CPUE for wild Lake Sturgeon and hatchery-reared Lake Sturgeon were as follows:

- 1.71 LKST/100 m/24 h ( $\mathrm{n}=111$ ) for wild Lake Sturgeon; and
- $1.81 \mathrm{LKST} / 100 \mathrm{~m} / 24 \mathrm{~h}(\mathrm{n}=118)$ for hatchery-reared Lake Sturgeon (Table 8).

### 4.3.1 Year-Class Strength

Ageing structures were collected from 84 of the 216 juvenile fish captured, while 118 were known-age hatchery fish, and 10 were not aged in 2019 but had been aged in a previous year. The ages of four adult fish were also known and were included in the analysis. Thus, ages were assigned to 212 juvenile and four adult Lake Sturgeon, including 98 wild and 118 hatcheryreared fish.

Aged Lake Sturgeon (including both wild and hatchery) ranged from 1-11 years old (i.e., 20082018 cohorts). The 2018 cohort (age-1) was the most frequent in the catch accounting for $38.9 \%(n=84)$ of the aged fish (Figure 11). The 2014, 2015, and 2016 cohorts (ages 5, 4, and 3) were the next most abundant age-classes, representing $13.0 \%(\mathrm{n}=28), 15.3 \%(\mathrm{n}=33)$, and $13.0 \%(n=28)$ of the catch, respectively (Figure 11). Hatchery-reared Lake Sturgeon accounted for the majority of the 2014 cohort ( $\mathrm{n}=20 ; 71.4 \%$ ) and the entire 2018 cohort ( $\mathrm{n}=84$; Figure 11). Wild fish from the 2009, 2018, and 2019 (YOY) cohorts were not captured in 2019; however, wild fish from all cohorts between 2000 and 2017 have been present in the catch since studies began (Table 6).

### 4.3.2 POPULATION Estimate

The 2019 population estimate for Stephens Lake was 857 wild juvenile Lake Sturgeon ( $95 \% \mathrm{CI}$ : 517-1,420) (Figure 12; Appendix A5-4). This was above the $95 \% \mathrm{Cl}$ of the 2010 and 2012 estimates, but within those of 2013-2018. The estimated annual survival rate was $79 \%$.

Survival of hatchery-reared Lake Sturgeon stocked into Stephens Lake was estimated at 93\% (Appendix A5-5). Based on this survival estimate, 309, 619, and 390 hatchery-reared individuals from the 2014, 2016, and 2018 cohorts are present in Stephens Lake, contributing to a population estimate of 1,318 hatchery fish. Based on these numbers, it is estimated that hatchery fish currently make up $61 \%$ of the total juvenile Lake Sturgeon population in Stephens Lake.

### 4.3.3 GROWTH AND CONDITION

Length-weight relationships for hatchery-reared and wild Lake Sturgeon are presented in Figure 3.

Wild Lake Sturgeon had a:

- Mean FL of 542 mm ( $\mathrm{n}=111$; StDev = 175 mm ; range 287-1,060 mm);
- Mean weight of $1,608 \mathrm{~g}(\mathrm{n}=110 ;$ StDev $=1,821 \mathrm{~g}$; range $100-11,500 \mathrm{~g})$; and
- Mean condition factor of $0.71(n=110 ; \operatorname{StDev}=0.11$; range $0.32-1.01)$ (Table 9).

Wild Lake Sturgeon in the 450-499 mm FL interval were captured most frequently accounting for $25.2 \%(n=28)$ of the wild catch. The 350-399 mm FL intervals was also caught frequently and accounted for $15.3 \%$ ( $\mathrm{n}=17$; Figure 8).

Hatchery-reared Lake Sturgeon had a:

- Mean FL of $354 \mathrm{~mm}(\mathrm{n}=118$; StDev $=92 \mathrm{~mm}$; range 261-506 mm);
- Mean weight of $318 \mathrm{~g}(\mathrm{n}=118$; StDev $=330 \mathrm{~g}$; range $75-1,300 \mathrm{~g})$; and
- Mean condition factor of $0.54(\mathrm{n}=118 ; \operatorname{StDev}=0.12$; range $0.29-1.03)$ (Table 10).

Hatchery-reared Lake Sturgeon in the 300-349 mm ( $\mathrm{n}=43$; 36.4\%) and $250-299 \mathrm{~mm}(\mathrm{n}=40$; 33.9\%) FL intervals were captured most frequently (Figure 8).

Growth curves of juvenile Lake Sturgeon captured during baseline (2008-2012) and construction (2014-2019) could not be compared due to low catches during baseline sampling. Growth curve analysis of hatchery and wild fish showed that young hatchery fish ( $0-2$ years-old) are longer than wild fish of the same cohort. However, the lengths of wild and hatchery fish appear similar around age-5 (Figure 13).

### 4.3.4 RECAPTURES

A total of 24 wild Lake Sturgeon tagged in a previous year were recaptured in Stephens Lake in 2019 (Table 11; Appendix A4-1). Of these: four were tagged in 2011, one in 2012, three in 2014, one in 2015, three in 2016, seven in 2017, and five in 2018.

Recaptured fish moved varying distances from their original capture locations:

- Twenty-two fish were originally captured in Stephens Lake. Eleven within 1.0 km of their initial capture location and eleven between 1.1 and 3.2 km of their initial capture location.
- Two fish were originally tagged in the future Keeyask reservoir (Zone GL-C):
- Floy \#93874 was tagged on September 21, 2011, 14.2 km upstream of its recapture location. It increased in size by 394 mm and $1,700 \mathrm{~g}$ in eight years since its initial capture.
- Floy \#116848 was tagged on September 15, 2014, 14.4 km upstream of its recapture location. It increased in size by 347 mm and $1,075 \mathrm{~g}$ in five years since its initial capture.

### 4.3.5 HATCHERY CAPTURES

A total of 118 hatchery-reared Lake Sturgeon released as one-year-olds were captured in Stephens Lake in 2019, representing $51.5 \%$ of the total catch (Table 12). None of the hatcheryreared fish had been captured during previous sampling. An age breakdown of all the hatcheryreared fish captured between 2014 and 2018 is presented in Table 13.

Of the 118 hatchery captures (Appendix A4-3):

- A total of 105 were stocked in Stephens Lake (Map 8):
- Eighteen were stocked in 2015.
- Eleven were stocked at Site 3 in Zone STL-B on June 22 all but one of which were caught upstream of their stocking location.
- Four were stocked at Site 4 in Zone STL-B on September 14 and were recaptured within 1.0 km of their stocking location; and
- Three were stocked at Site 5 in Zone STL-A on September 14 and were recaptured between 1.7 and 2.0 km of their stocking location.
- Nine were stocked in 2017.
- Six were stocked on June 15 in Zone STL-A (Site 1) of which all were caught between 3.9 and 4.9 km downstream of their stocking location; and
- Three were stocked on October 5 in Zone STL-B (Site 4) of which one was caught 0.8 km upstream and two were caught downstream (1.7 km and 1.9 km).
- Seventy-eight were stocked in 2019.
- Forty-three were stocked in Zone STL-A on June 13 (Site 1). Forty were caught between 0.1 and 2.8 km downstream of their stocking location and three were caught upstream (between 0.9 and 3.0 km ); and
- Thirty-five were stocked in Zone STL-B on June 13 (Site 2). All 35 fish were caught within 1.3 km of their release location.
- Eleven were stocked in Gull Lake (Map 6):
- Two were stocked on September 16, 2015 in Zone GL-B (Site 6). They were recaptured 14.8 and 15.2 km downstream of their stocking location.
- Four were stocked in 2017.
- Three were stocked on June 8 in Zone GL-A (Site 1) and were recaptured 24.8 km downstream of their stocking location; and
- One was stocked on June 15 in Zone GL-A (Site 1) and was recaptured 24.8 km downstream of its stocking location.
- Five were stocked on June 6, 2019.
- Three in Zone GL-C (Site 1) were recaptured between 13.1 and 14.5 km downstream of their stocking location; and
- Two in Zone GL-B (Site 2) were recaptured 15.6 and 15.8 km downstream of their stocking location.
- One fish was stocked in the Burntwood River on October 2, 2014 (Site 3; Map 4). The fish was recaptured 138.0 km downstream of its stocking location and grew 172 mm in FL and 396 g in weight. This fish represents the first hatchery-reared fish stocked in the Burntwood River to be caught in Stephens Lake.
- One fish (PIT \# 900 067000109606) was stocked in June 2019, however, its stocking location was not recorded. This fish may have been stocked in either the future Keeyask reservoir or Stephens Lake.

### 5.0 DISCUSSION

### 5.1 Juvenile Abundance

Juvenile abundance in the upper Split Lake Area has been highly variable since sampling began. Although 1,357 age-1 fish have been stocked in this area since 2014, only five were captured prior to 2018. As a result, gillnetting effort was increased in deep water channels of Split Lake in 2018 and 2019 to determine whether stocked fish were moving downstream out of the Burntwood River into Split Lake. Sampling conducted in 2018 in deep habitat along the north shore yielded few Lake Sturgeon. Gillnetting effort in 2019 was focussed along the southern portion of Split Lake in a deep channel that was thought to receive flow from both the Burntwood and Nelson rivers, and where both hatchery and wild fish were captured in 2018. The 2019 Split Lake catch was the highest since studies began in 2015, with CPUE more than double that recorded in 2018. It is unclear whether the majority of fish captured were spawned in the Burntwood, Nelson, or Grass rivers; however, recaptured fish were originally tagged in the Burntwood River, Split Lake, and the future Keeyask Reservoir. Further, the presence of fish stocked in the Burntwood River indicates that at least some fish from this area move downstream into Split Lake.

While the new sites sampled in Split Lake yielded more fish than in previous years, catches in the Burntwood River have decreased over the last two study years. High flows and increased debris levels have likely affected the ability to sample the Burntwood River effectively, thus it is possible Lake Sturgeon are present but are not being captured.

In 2019, a population estimate was produced for the first time for the Upper Split Lake Area. Unlike the adult population estimates, a single value was produced for all of Upper Split Lake as the large majority of juveniles are captured in Split Lake proper and may originate in either the Nelson River below Kelsey or the Burntwood River. The 2019 estimate for the Upper Split Lake Area was 4,503 wild juveniles ( $95 \% \mathrm{Cl}: 1,348-15,044$ ) with a survival estimate of $82 \%$. Because this was the first year this estimate was generated, the confidence intervals are very large. Estimates will change and confidence intervals will narrow as data are added to the model and estimates become more refined. A continued effort will be maintained in the area to determine population trends.

The population in the future Keeyask reservoir was estimated at 2,819 wild juveniles ( $95 \% \mathrm{Cl}$ : 1,529-5,199) in 2019, which was lower (but within the 95\% CI) than the estimate in 2018. Survival in the future Keeyask reservoir was measured at $74 \%$. Annual population estimates have fluctuated each study year but have remained relatively consistent since 2014. Total Lake Sturgeon CPUE has also remained relatively stable since 2014, ranging from 2.3 Lake Sturgeon/100 m net/24 h in 2016 to 3.8 Lake Sturgeon in 2019. Total CPUE in 2019 was higher than in any study year since 2011. Although hatchery fish made up a large proportion of the

Aquatic Effects Monitoring Plan
catch (23\%), CPUE of wild fish was higher in 2019 (2.9 Lake Sturgeon) than in either 2018 (2.2 Lake Sturgeon) or 2017 (2.3 Lake Sturgeon).

The population in Stephens Lake was estimated at 857 wild individuals ( $95 \% \mathrm{CI}$ : $517-1,420$ ), which was lower (but within the $95 \% \mathrm{Cl}$ ) than the estimate in 2018. Annual population estimates have fluctuated each study year but have remained relatively consistent since 2014. Survival in Stephens Lake was measured at $79 \%$. Hatchery-reared fish made up a large proportion of the total catch (51\%), however, the CPUE of wild fish (1.7 Lake Sturgeon) in 2019 remained high when compared to 2018 (0.8 Lake Sturgeon) and 2017 (1.2 Lake Sturgeon).

### 5.2 RECRUITMENT

Recruitment has occurred in all three sampling areas since construction of the Keeyask GS began in 2014. Capture of fish between 0 and 3 years old provides a short-term indication of spawning and recruitment success of early life stages. However, given that these ages are not fully vulnerable to the sampling gear, the absence of fish does not conclusively indicate that none are present. In 2019, 105 wild Lake Sturgeon aged between 0 and 3 were caught: 17 in the Upper Split Lake Area, 64 in the future Keeyask reservoir, and 24 in Stephens Lake.

In 2019, no YOY or age-1 Lake Sturgeon were caught in Stephens Lake. Based on similarities in cohort frequency data as well as genetic evidence (Gosselin et al. 2016), Henderson et al. (2015) hypothesized recruitment to the Stephens Lake population was mainly due to spawning upstream of Gull Rapids (i.e., in the future Keeyask reservoir). However, more recent results indicate the cohort frequency distribution in Stephens Lake differs from that in the future Keeyask reservoir. For example, the 2015 cohort is strong in Stephens Lake but not in the future Keeyask reservoir. Burnett et al. (2018) hypothesized that if these fish had been spawned upstream of Gull Rapids and drifted downstream, a larger proportion would have remained upstream. Further, adult spawning studies have shown a recent increase in the number of mature males captured during spring adult surveys below Gull Rapids (Legge et al. 2017; Holm and Hrenchuk 2019). Despite the absence of captures from the 2018 and 2019 year classes to date, they may still be captured in future sampling years.

### 5.3 HATCHERY FISH

Stocking began in the Burntwood River in 2014. Catches of hatchery-reared fish (i.e., fish released at age-1 marked with PIT tags) originally stocked in the Burntwood River ('Burntwood stocked fish') increased in 2019, however, none were caught within the Burntwood River itself. Prior to 2019, six Burntwood stocked fish ( $0.4 \%$ of stocked fish) were captured in the Upper Split Lake Area: one in 2014, one in 2016, three in 2017, and one in 2018. An additional four Burntwood stocked fish ( $0.3 \%$ of stocked fish) were caught in the future Keeyask reservoir. In 2019, a total of 10 Burntwood stocked fish were caught in Split Lake and an additional three
were caught further downstream (two in the future Keeyask reservoir and one in Stephens Lake). The fish caught in Stephens Lake represents the furthest downstream movement recorded to date. An additional two Burntwood stocked fish were captured in the Burntwood River during the spring 2019 adult Lake Sturgeon studies (Ambrose et al. 2020). Similar to previous years, the low catch of hatchery fish in the Burntwood River suggests the majority of stocked yearlings are dispersing downstream.

Stocking in the Keeyask area began in 2015 with 1,284 age-1 fish released to date in the future Keeyask reservoir ('Keeyask stocked fish'). The number of hatchery fish caught in 2019 was more than triple ( $n=57 ; 23 \%$ ) the number captured in 2018 ( $n=17 ; 11 \%$ ) accounting for $47 \%$ ( $\mathrm{n}=27$ ) of the total catch.

As of 2019, 1,528 age-1 hatchery-reared Lake Sturgeon have been released in Stephens Lake ('Stephens stocked fish'). Hatchery-reared Lake Sturgeon caught in Stephens Lake in 2019 ( $\mathrm{n}=118$ ) accounted for more fish than in any previous year. Hatchery-reared fish accounted for $52 \%$ of the total catch and made up the entire age-1 year-class ( $\mathrm{n}=85$ ). To date, hatchery fish have been more prevalent in the catch in both the future Keeyask reservoir and Stephens Lake in stocking years (i.e., prior to their first winter outside of the hatchery).

As in previous study years, some fish stocked in the future Keeyask reservoir were caught in Stephens Lake. Of the captured hatchery-reared fish originally stocked in the future Keeyask reservoir, $16 \%(n=3)$ were captured in Stephens Lake in 2018, while $17 \%(n=11)$ were captured in Stephens Lake in 2019. This pattern of downstream movement has not been documented for recaptured wild fish. Only five wild juvenile Lake Sturgeon originally tagged in the future Keeyask reservoir have been captured in Stephens Lake since studies began, two of which were captured in 2019.

### 5.4 Key Questions

The AEMP identified key questions for juvenile Lake Sturgeon monitoring, four of which are relevant to the construction period and are addressed in the discussion below.

Does recruitment of wild sturgeon occur upstream and/or downstream of the GS during construction?

In 2019, four wild YOY sturgeon were caught in the future Keeyask reservoir and none were caught in Stephens Lake. While the presence of four YOY sturgeon in the future Keeyask reservoir indicates successful spawning occurred upstream of the Keeyask GS, the absence of YOY in Stephens Lake does not necessarily mean recruitment was unsuccessful downstream. YOY are often underrepresented in the catch due to their size and the gear used does not adequately target YOY fish. No wild fish from the 2018 cohort (age-1) were caught in Stephens Lake in 2019 and only one was caught in the future Keeyask reservoir. All other cohorts spawned since construction started (i.e., 2015-2017) have been present in the catch in both waterbodies.

Aquatic Effects Monitoring Plan

Is there a biologically meaningful (and statistically significant) change in condition factor and growth of juvenile sturgeon during construction?

Condition factor of juvenile Lake Sturgeon sampled in all three study areas in 2019 were within the ranges observed in previous years. Comparison of growth curves of wild fish captured in the future Keeyask reservoir during baseline and construction indicated growth during both time periods was similar. Too few juveniles were collected in Stephens Lake prior to construction to support a pre/post analysis.

Two questions related to the stocking program are addressed below:

- What is the survival rate of stocked sturgeon?
- What is the proportion of hatchery-reared to wild recruits within a cohort (i.e., how successful is the stocking program)?

Only sturgeon stocked as yearlings can be distinguished from wild fish and the following discussion considers only these fish. In 2019, the annual survival rate of stocked sturgeon was estimated at $83 \%$ in the future Keeyask reservoir and $93 \%$ in Stephens Lake. The population of hatchery-reared Lake Sturgeon in the future Keeyask reservoir was estimated at 912 individuals ( $24 \%$ of the total juvenile population). The estimate of hatchery-reared fish in Stephens Lake was higher ( 1,318 individuals) and the proportion of the juvenile Lake Sturgeon population made up of hatchery-reared fish was $61 \%$.

The proportion of hatchery-reared to wild Lake Sturgeon captured in both the future Keeyask reservoir and Stephens Lake in 2019 appears to be increasing. In the future Keeyask reservoir, the proportion of hatchery-reared Lake Sturgeon in the catch has increased from 2\% in 2015 to 23\% in 2019. Similarly, in Stephens Lake, hatchery captures have increased from 7\% in 2015 to 52\% in 2019. Further, in 2019, the CPUE of hatchery-reared Lake Sturgeon in Stephens Lake was higher than that of wild fish. Hatchery-reared fish dominated the 2018 cohort in the future Keeyask reservoir (96\%) and the 2014 and 2018 cohorts in Stephens Lake (71\% and 100\%, respectively).

Too few hatchery-reared fish stocked in the Burntwood River were captured to calculate a survival and population estimate. However, ten of these fish were captured in Split Lake in 2019, which marks the largest number captured in a single year since stocking began in 2014. Hatchery-reared fish made up 6\% of the Lake Sturgeon catch in Split Lake and 0\% of the catch in the Burntwood River in 2019.

The recapture of stocked fish indicates hatchery-reared sturgeon are growing and surviving in the wild. Hatchery fish released as one-year olds are longer at release than wild fish of the same age, and this "head start" appears to persist until approximately age-5 when hatchery and wild fish are approximately the same size.

### 5.5 Next Steps

The juvenile Lake Sturgeon monitoring program will be repeated in 2020.
Sampling locations and effort in the Burntwood River will remain similar to previous years. Due to the success of locating more wild and hatchery fish in Split Lake in 2019, increased gillnetting effort in Split Lake (downstream of the Nelson and Burntwood rivers) will continue. Sites in Split Lake will include those that captured fish in 2019 as well as new locations within the channel along the southern shore of the lake (i.e., east of sites sampled in 2019). Sampling in the future Keeyask reservoir and Stephens Lake will remain similar to previous years unless impoundment occurs immediately prior to the fall program, in which case sampling locations will be adjusted based on site conditions and catches.

Growth of hatchery fish will continue to be monitored using von Bertalanffy growth curves with growth estimates likely to become more refined as the length of time hatchery fish have spent in the wild increases. Population estimates will continue to be updated as more mark recapture data becomes available.

### 6.0 SUMMARY AND CONCLUSIONS

- Sampling locations in the Burntwood River, the future Keeyask reservoir, and Stephens Lake remained similar to previous years. As in 2018, sampling was not conducted in the Kelsey GS area, as effort was shifted to Split Lake in an attempt to capture stocked fish. Gillnetting effort in 2019 was focussed along the southern portion of Split Lake in a deep channel that was thought to receive flow from both the Burntwood and Nelson rivers and where both hatchery and wild fish were captured in 2018.
- A total of 182 Lake Sturgeon were captured in the Upper Split Lake Area: 19 (all juveniles) in the Burntwood River (641.4 gillnet hours, CPUE of 0.7 Lake Sturgeon/100 m net/24 h) and 163 (141 juvenile and 22 adult) in Split Lake (722.7 gillnet hours, CPUE of 5.4 Lake Sturgeon/100 m net/24 h). The 2013 cohort was the most common captured. Twenty-one previously tagged Lake Sturgeon were captured in Split Lake while none were captured in the Burntwood River. Of the 21 recaptured fish, ten were Burntwood stocked fish: two were released in 2014 (2013 cohort) and eight in 2018 (2017 cohort). No YOY (2019 cohort) were caught in the Upper Split Lake Area in 2019.
- In the future Keeyask reservoir, 244 (234 juvenile and ten adult) Lake Sturgeon were captured in $1,560.6$ gillnet hours for a total CPUE of 3.8 Lake Sturgeon/100 m net/24 h. Aged Lake Sturgeon ( $\mathrm{n}=228$ ) ranged from 0 to 13 years old with three-year-old fish (2016 cohort) the most prevalent in the catch ( $\mathrm{n}=60 ; 26.3 \%$ ). A total of 21 Lake Sturgeon tagged in previous years and 57 stocked yearlings were captured. Twelve of the re-captured Keeyask stocked fish were released in 2015 (2014 cohort), 17 were released in 2017 (2016 cohort), and 27 were released in 2019 (2018 cohort). An additional two Burntwood stocked fish (one in 2014 and one in 2018) were captured in the future Keeyak reservoir, 111 km and 129 km downstream of their release locations.
- In Stephens Lake, 229 (216 juvenile and 13 adult) Lake Sturgeon were captured in $1,560.9$ gillnet hours for a total CPUE of 3.5 Lake Sturgeon $/ 100 \mathrm{~m}$ net/24 h. Lake Sturgeon ages ranged from 1 to 11 with the 2018 cohort (age-1) captured most frequently ( $n=84 ; 38.9 \%$ ). A total of 24 Lake Sturgeon tagged in a previous year and 118 stocked yearlings were captured. Most of the recaptures were Stephens stocked fish released in 2019 ( $\mathrm{n}=78$; 2018 cohort) but an additional 18 were released in 2015 (2014 cohort) and nine were released in 2017 (2016 cohort). The stocking location for one hatchery fish, known to be from the 2018 cohort, is unknown. Ten recaptures were Keeyask stocked fish: two released in 2015, four in 2017 and five in 2019. One hatcheryreared fish was stocked 138 km upstream in the Burntwood River in 2014 and is the first Burntwood stocked fish captured in Stephens Lake.
- Abundance estimates were calculated for wild juvenile Lake Sturgeon in all three sampling areas. The population estimate in 2019 was 4,503 wild juvenile Lake Sturgeon (95\% CI: 1,348-15,044) for the Upper Split Lake Area, 2,819 (95\% CI: 1,529-5,199) for
the future Keeyask reservoir, and 857 ( $95 \%$ CI: 517-1,420) for Stephens Lake. Survival was estimated as $82 \%, 74 \%$, and $79 \%$ in the Upper Split Lake Area, future Keeyask reservoir, and Stephens Lake, respectively.
- The key questions, as described in the AEMP, for juvenile Lake Sturgeon population monitoring during construction of the Keeyask GS are as follows:
- Does recruitment of wild sturgeon occur upstream and/or downstream of the GS during construction?

In 2019, four wild YOY sturgeon were caught in the future Keeyask reservoir. Wild sturgeon spawned during each year of construction (2015-2019) have been captured during the study. In Stephens Lake, wild representatives from the 2018 cohort have been absent from the catch in the last two study years and no YOY fish were caught in 2019; however, the 2015-2017 cohorts are present.

- Is there a biologically meaningful (and statistically significant) change in condition factor and growth of juvenile sturgeon during construction?

Condition factor of juvenile Lake Sturgeon sampled in all three study areas in 2019 were within the ranges observed in previous years. Comparison of growth curves of wild fish captured in the future Keeyask reservoir during baseline and construction indicated growth during both time periods was similar. Too few juveniles were collected in Stephens Lake and the Upper Split Lake Area prior to construction to support a pre/post analysis.

- What is the survival rate of stocked sturgeon? What is the proportion of hatcheryreared to wild recruits within a cohort (i.e., how successful is the stocking program)?

The survival rates of stocked sturgeon in the future Keeyask reservoir and Stephens Lake were 83\% and 93\%, respectively. In the future Keeyask reservoir, the proportion of hatchery-reared Lake Sturgeon in the catch increased from $2 \%$ in 2015 to $23 \%$ in 2019, more than double the value in 2018 (11\%). Hatchery captures in Stephens Lake have risen from $7 \%$ in 2015 to more than half of the catch in 2019 (52\%). Further, in 2019, the CPUE of hatchery-reared Lake Sturgeon in Stephens Lake was higher than that of wild fish. Hatchery-reared fish dominated the 2018 cohort in the future Keeyask reservoir (96\%) and the 2014 and 2018 cohorts in Stephens Lake ( $71 \%$ and 100\%, respectively).

In contrast to the Keeyask and Stephens Lake areas, catches of hatchery-raised fish in the Upper Split Lake have been low. Beginning in 2018, sampling was extended into Split Lake in an attempt to determine whether stocked fish had moved downstream. In 2019, ten stocked fish (the largest number collected in one year) were captured at sites in a deep channel along the southern margin of Split Lake, downstream of the Burntwood River and Nelson River. Sampling in 2020 will target these locations as well as additional sites in Split Lake to determine whether sturgeon stocked into the Burntwood River are surviving.

a - Gillnet set durations were standardized to 100 m of net and then summed to calculate the total gillnet hours for each study.
b- Does not include Lake Sturgeon recaptured more than once in the same study.
c - Removed from sampling in 2018.
d - Birthday Rapids to Gull Rapids.
 indicate cohorts not present in the corresponding study year. The Kelsey GS area was not sampled and more sampling sites were added to Split Lake in 2019 in an attempt to locate hatchery-reared fish stocked in the Burntwood River. Ageing Structures from the Burntwood River in 2014 were not ageable.

a - Fish released in the Burntwood River and caught in the same area
b - Fish released in the Burntwood River but caught in Split Lake
c - Fish released in the Burntwood River.

## FIGURES

Aquatic Effects Monitoring Plan

Figure 1: Cohort frequency distribution by zone, for all aged Lake Sturgeon captured in the Burntwood River, fall 2019. Cohorts prior to 2010 (i.e., age-9 fish) are not fully represented as ageing structures are not collected from fish > $\mathbf{8 0 0} \mathbf{~ m m}$ fork length (indicated by vertical dashed line). See Map $\mathbf{3}$ for location of zones.

Figure 2: Length-frequency distributions for Lake Sturgeon captured in gill nets set in the Upper Split Lake Area: A) the Burntwood River and B) Split Lake, fall 2019.

Figure 3: Comparison of weight (g) at-fork length (mm) (log transformed) for Lake Sturgeon captured in: A) the Upper Split Lake Area B) the future Keeyask reservoir and C) Stephens Lake, fall 2019.

Figure 4: Cohort frequency distributions for all aged Lake Sturgeon captured in Zone SPL-A of Split Lake, fall 2019. Cohorts prior to 2010 (i.e., age-9 fish) are not fully represented as ageing structures are not collected from fish $\mathbf{8} \mathbf{8 0 0} \mathbf{~ m m}$ fork length (indicated by vertical dashed line).

Figure 5: Juvenile Lake Sturgeon abundance (i.e., fish < 800 mm fork length) estimates based on POPAN best model for the Upper Split Lake Area (2012-2019). Each red x marks the estimated abundance for each year (i.e., the number of juvenile Lake Sturgeon), the black dots represent the min and max estimates, and the vertical bar lines represent the upper and lower $95 \%$ confidence range.

Figure 6: Cohort frequency distributions for all aged Lake Sturgeon captured by zone in the future Keeyask reservoir (A) and by hatchery and wild Lake Sturgeon (B), fall 2019. Cohorts prior to 2010 (i.e., age-9 fish) are not fully represented as ageing structures are not collected from fish $\mathbf{> 8 0 0} \mathbf{~ m m}$ fork length (indicated by vertical dashed line). See Map 5 for zones.

Figure 7: Juvenile Lake Sturgeon abundance (i.e., fish < $\mathbf{8 0 0} \mathbf{~ m m}$ fork length) estimates based on POPAN best model for the future Keeyask reservoir (2010-2019). Each red x marks the estimated abundance for each year (i.e., the number of juvenile Lake Sturgeon), the black dots represent the min and max estimates, and the vertical bar lines represent the upper and lower $95 \%$ confidence range.

Fork Length Interval (mm)

Figure 8: Fork length frequency distributions for Lake Sturgeon captured in gill nets set in: A) the future Keeyask reservoir and B) Stephens Lake, fall 2019.

Figure 9: $\quad$ Fork length-at-age (A) and von Bertalanffy growth curve analysis (B) for all Lake Sturgeon caught during baseline (red; 2008-2012) and construction (blue; 2014-2019) monitoring years in the future Keeyask reservoir. Fish older than age- 9 were not included in the analysis as they are not fully represented in the catch (ageing structures are not collected from fish >800 mm fork length, which corresponds to fish older than age-9).

Figure 10: Fork length-at-age (A) and von Bertalanffy growth curve analysis (B) for all wild (blue) and hatchery-reared (red) Lake Sturgeon released and/or recaptured in the future Keeyask reservoir since stocking began in 2014. The growth curve is truncated at age-5 as this is the maximum age of hatcheryreared fish.

## Cohort Year

Figure 11: Cohort frequency distributions for all aged Lake Sturgeon captured in Stephens Lake by zone (A) and by hatchery and wild Lake Sturgeon (B), fall 2019. Cohorts prior to 2010 (i.e., age-9 fish) are not fully represented as ageing structures are not collected from fish > $\mathbf{8 0 0} \mathbf{~ m m}$ fork length (indicated by vertical dashed line). See Map 7 for zones.

Figure 12: Juvenile Lake Sturgeon abundance estimates based on POPAN best model for Stephens Lake (2010-2019). Results of the POPAN abundance estimate are presented in black. Each red $x$ marks the estimated abundance for each year (i.e., the number of juvenile Lake Sturgeon), the black dots represent the min and max estimates, and the vertical bar lines represent the upper and lower $95 \%$ confidence range.

Figure 13: Fork length-at-age (A) and von Bertalanffy growth curve analysis (B) for all wild (blue) and hatchery-reared (red) Lake Sturgeon released and/or recaptured in the Stephens Lake since stocking began in 2014. The growth curve is truncated at age-5 as this is the maximum age of hatchery-reared fish.

## APPENDIX 3: <br> AGEING STRUCTURES OF JUVENILE LAKE STURGEON CAUGHT IN THE KEEYASK STUDY AREA.

Figure A3-1: Ageing structure from a wild juvenile Lake Sturgeon (8-year-old) caught in
Gull Lake. ..... 108

Figure A3-2: Ageing structure from a hatchery reared juvenile Lake Sturgeon caught in Stephens Lake (2-year-old). Agers noted the presence of a weak first annulus and false annuli typically observed in hatchery reared Lake Sturgeon.109

Table A5-5: Results of POPAN analysis of hatchery-reared juvenile Lake Sturgeon from Stephens Lake. Best model was constant survival and variable recapture. Confidence intervals are rounded ..... 151

Mark-recapture population estimates were calculated for wild fish in the Upper Split Lake Area, future Keeyask reservoir and Stephens Lake during the fall of nine different years (2010 and 2012-2019). Only wild Lake Sturgeon classified as juveniles (i.e., fork length less than 800 mm ) were included in the population estimate. All data for the period 2008-2012 were collected annually as part of environmental studies related to the pre-Project environment, while data from 2014 until 2044 will be collected annually as part of monitoring studies related to the Keeyask GS Project.

Data were analysed using the program MARK (White and Burnham 1999; Kendall 2001; Arnason and Schwartz 2002), which is an industry standard for the analysis of data from marked populations. Program MARK uses binary numbers to represent the encounter history of individuals, and then uses the cumulative pattern of 0's (not-encountered) and 1's (reencountered live capture) to generate a probability distribution of tag recaptures which form the basis of population estimation. Re-encounters can also be from dead recoveries (e.g., the animal is harvested) in which case the model uses a value of -1 . For example, the history "10-1" indicates than an animal was captured for the first time at sampling occasion 1, not encountered at sampling occasion 2 , and recovered dead at sampling occasion 3.

Several different population model variants exist, most of which can be classified as either closed or open models. Closed models assume there are no births, deaths, immigration, or emigration between sample periods, while open models assume these processes occur. The Jolly-Seber model (POPAN formulation; Arnason and Schwarz 2002), as implemented within MARK, was used to estimate the annual abundance of juvenile Lake Sturgeon. This is an open model that requires few assumptions and modeled variables, and thus likely provides a reliable estimate of abundance.

Using first-time capture and recapture information, POPAN estimates the survival (i.e., the probability that a fish will survive from one capture to the next), the probability of recapture ( p ; i.e., the probability that a fish will be recaptured given that the animal is alive and in the study area), and abundance ( N ; i.e., the number of juvenile Lake Sturgeon in the area during each capture period) (Tables A5-1, A5-2 and A5-4).

- Model fit for survival was calculated as 83\% for the Upper Split Lake Area, 74\% for the future Keeyask reservoir and 79\% for Stephens Lake.
- The probability of recapture varied among years:
- Recapture rates were split into six groups based on the model for the Upper Split Lake Area: i) 2012 (0.87); ii) 2013 (0.00); iii) 2014 (0.06); iv) 2015-2016 (0.01); v) 2017-2018 (0.02); and vi) 2019 (0.03).
- For the future Keeyask reservoir rates were split into six groups: i) 2010 (0.45); ii) 2012 (0.08); iii) 2013 (0.02); iv) 2014-2016 (0.03); v) 2018 (0.04); and vi) 2017 and 2019 (0.06).
- For Stephens Lake, recapture rates were split into eight groups: i) 2010 (1.00); ii) 2012 (0.24); iii) 2013 (0.04); iv) 2014 (0.08); v) 2015 (0.06); vi) 2016 and 2019 (0.11); vii) 2017 (0.12); and viii) 2018 (0.05).
- Abundance estimates for the Upper Split Lake Area are provided for the 2012-2019 study years and for the future Keeyask reservoir and Stephens Lake are provided for the 2010 and 2012-2019 study years.
- As sampling continues (i.e., year to year) and data is added to the model, the parameters are recalculated. Thus, although survival rates and abundance estimates are calculated for the same time periods, they may differ among reporting periods. This allows the estimates to become more refined and precise over time.

The Cormack-Jolly-Seber model was used to calculate an estimate of survival of hatcheryreared lake Sturgeon in both the future Keeyask reservoir and Stephens Lake between 2015 (when stocking began) and 2019. This model calculates an estimate using the probability of recapture. For example if 426 juveniles were stocked in a system and the estimated survival rate was 0.93 over three years then the remaining number of hatchery fish in the system would be calculated by multiplying the number of stocked fish by the survival rate over three years. The resulting number would be calculated as follows: ( 426 hatchery fish) $\times(0.93) \times(0.93) \times$ $(0.93)=342$ and would represent the number of hatchery fish estimated to still be present in the system after three years.
